

Advancing health
equity among rural
residents through
translational
health behavior
research

Nancy E. Schoenberg, Ph.D.

Marion Pearsall Professor of Behavioral Science

Director, Center for Health Equity Transformation (CHET)

University of Kentucky

nesch@uky.edu

 Center for
Health Equity
Transformation

Objectives

Upon completion of this presentation, you will be able to:

- Define and describe health challenges in rural contexts
- Improve your understanding of cultural adaptation of evidence-based interventions
- Describe translational behavioral approaches designed to mitigate such inequities, including community-based interventions

Disclosure

Dr. Schoenberg has no relevant financial relationships to disclose and does not plan to discuss the off-label use of a product.

Some background on rural US

The 46 million U.S. residents living in rural areas in 2020 made up 14 percent of the U.S. population.

65% of rural residents live west of the MS river, but only 10% of Westerners are considered rural

Nearly half (28 million, 47%) of the rural population lives in the South.

Highest % of rural residents (61%): ??

Lowest % of rural residents (5%): ??

Definitions:

“All counties that are not part of a Metropolitan Statistical Area (contains an urban core area of 50,000+ population).” - Office of Management and Budget

“Any population, housing, or territory not in an urban area (population between 2,500 and 50,000).” - Census Bureau

Some emergent trends in rural US

<https://health.gov/healthypeople/priority-areas/social-determinants-health>

Poverty rates by metro/nonmetro residence, 1959-2019

Note: Metro status of some counties changed in 1984, 1994, 2004, 2014, and 2018.
*CPS poverty status is based on family income in prior year and ACS poverty status is based on family income in the past 12 months.
Sources: USDA, Economic Research Service using data from U.S. Department of Commerce, Bureau of the Census, Current Population Survey (CPS) 1960-2013 and annual American Community Survey (ACS) estimates for 2007-19.

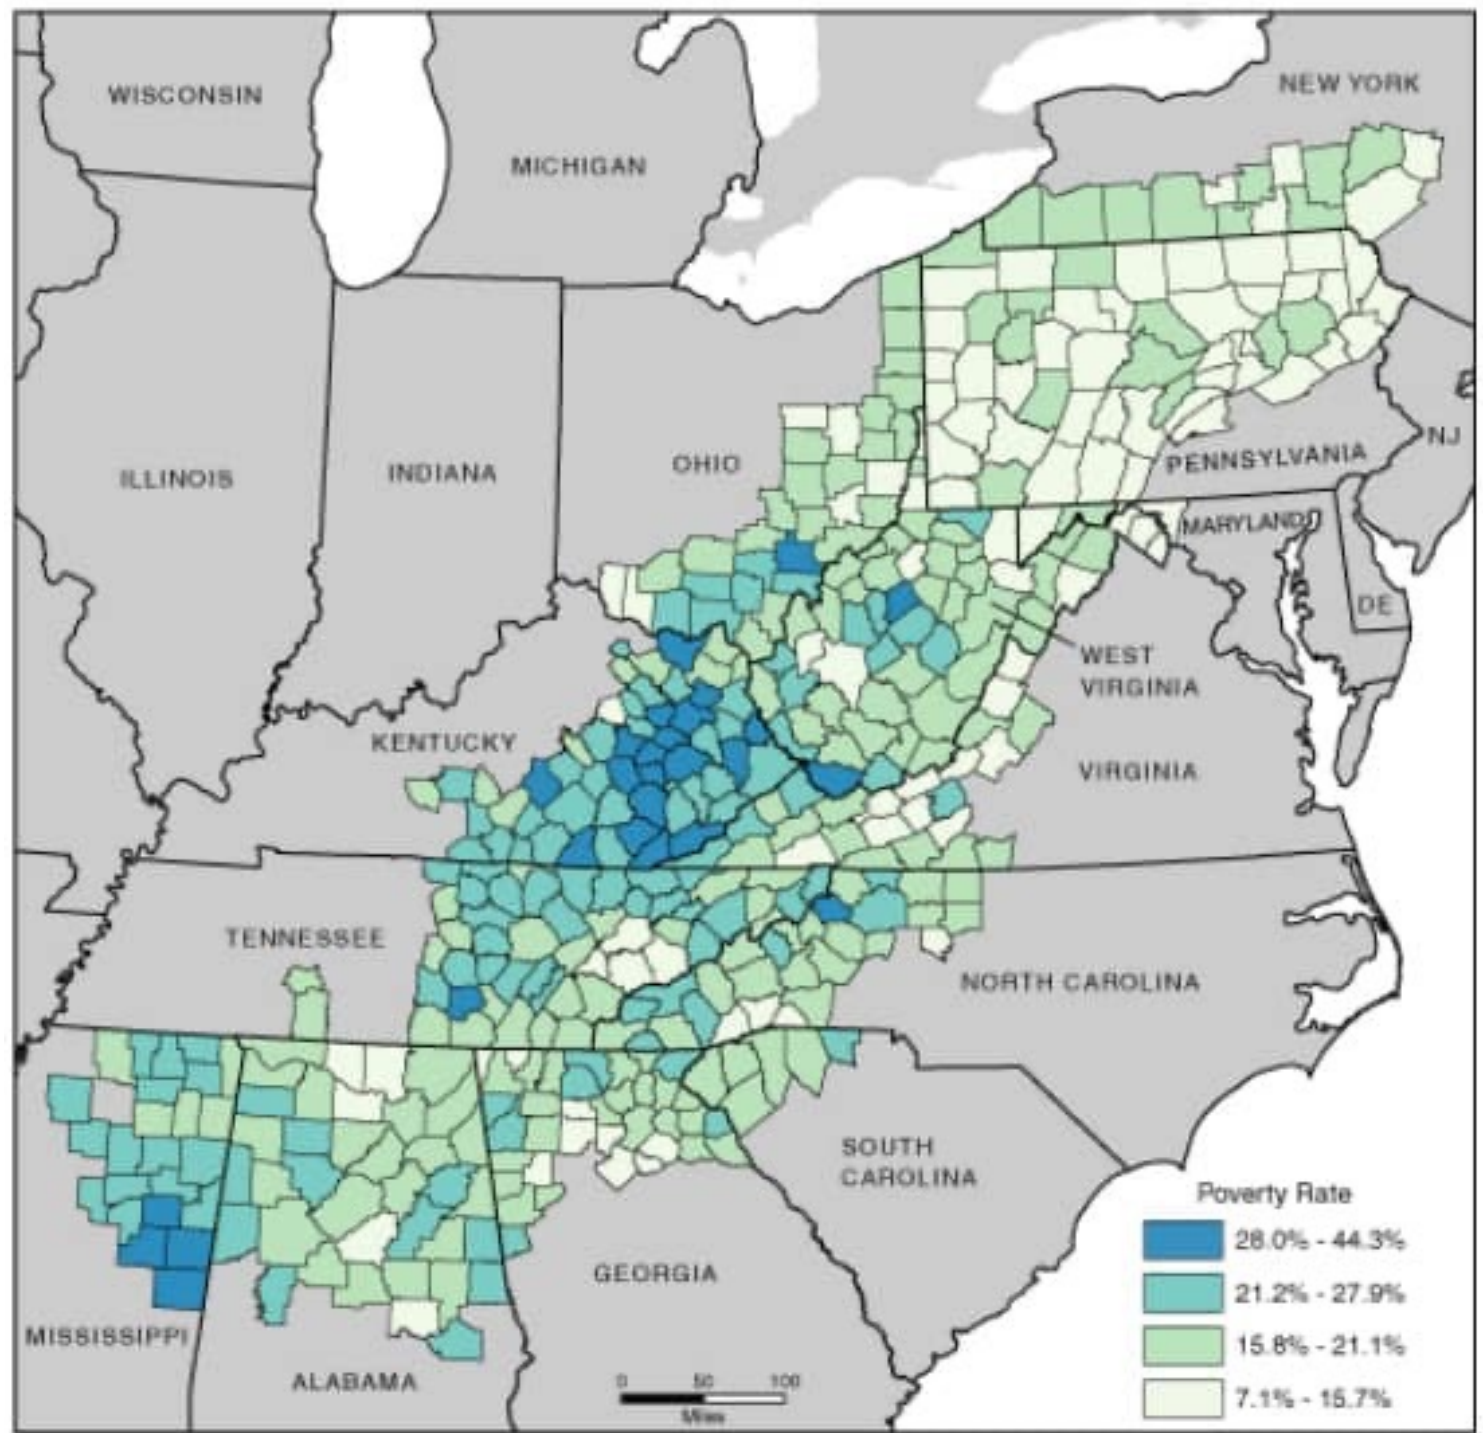

Age-adjusted death rates for 10 leading causes of mortality by rural-urban classification, US 2019

Figure 3. Age-adjusted death rates for the 10 leading causes of death, by urban-rural classification: United States, 2019

NOTES: Urbanicity of county of residence is based on the 2013 NCHS Urban-Rural Classification Scheme for Counties; see Data source and methods. Causes of death are ranked according to the number of deaths for the total population. Rates for all causes in rural areas were significantly higher than rates in urban areas ($p < 0.05$). Access data table for Figure 3 at: <https://www.cdc.gov/nchs/data/databriefs/db417-tables.pdf#3>. SOURCE: National Center for Health Statistics, National Vital Statistics System, Mortality.

- Financial incentives

UNIVERSITY OF KENTUCKY RESEARCH

Make Better Choices 2

If you live in Eastern Kentucky, researchers at the University of Kentucky are inviting you to participate in a healthy living study. Make Better Choices 2 (MBC2) employs technology to help you eat better, sleep better, and get more exercise. Participants will use a health app, Fitbits, and health coaching to change health behaviors. The goal of the study is to test whether MBC2 may promote healthy changes and prevent unnecessary sickness and death in people. MBC2 brings one of the most innovative new programs which may improve health to Eastern Kentucky.

Study participants will:

- Use a new health app and a Fitbit to track eating, stress, sleeping, exercise
- Work with a trained, local health coach
- Participate in 3 in-person health checks
- Receive \$ incentives for meeting goals

You may be eligible to participate if you:

- are willing to track your health behaviors with a Smartphone App and a Fitbit
- are 18 years or older

To complete survey, visit site at MakeBetterChoices2.com or scan QR code:

The Process of Adapting MBC2 to a Rural, Appalachian Population

Focus groups participants (N=4 groups, 38)

Key informant interviews (N=16)

CAB review and verification (N=9)

Wireframe processes with new key informants (N=8)

Usability survey administered to CAB (N=8)

Pilot testing (N=10)

RCT (N=350)

Adapting for Local Use

MBC2 Component	Local Challenge/ Preference	Adaptation
Eligibility criterion: age	Rural communities have older populations	Open up to all eligible people 18+--no upper age limits
Recruitment	Lack of urban recruitment sites (e.g., public transit)	Use social media, community locations (church, centers)
Smartphone	Concern about data costs; less tech experience	Special health coach training on data use/cost
Health Coaching	Sparse personal & local resources undermine behavior change	Local coaches have inventory to local food and activity resources, informed by community needs assessment
Individual-level intervention	Tight knit communities like group gatherings	Quarterly group events
App messaging	Fit Appalachian context	Highlight success stories, fun activities

Provocative questions remain...

- What is the true active ingredient in this mHealth intervention?
- Would in-person coaching be more effective than remote telehealth delivery?
- How sustainable are mHealth approaches in the absence of grant-funding?
 - How likely are mHealth or telehealth approaches to be included in health care or social service policy and programming?
 - How might evidence-based behavioral interventions become reimbursable?

Despite these efforts, interventions oftentimes do not achieve desired outcomes

Intersectionality/identity

and

Balance between fidelity to existing EBI
and adaptation

and

The ever evolving landscape: ex. NRT and
smoking cessation

And ...most trials fail to achieve desired outcomes

Clinical trials:

90% fail, likely due to:*

- lack of clinical efficacy (40-50%)
- unmanageable toxicity/side effects (30%)
- poor pharmacokinetic properties, (e.g., drug absorption/excretion) (10=15%)
- Lack of commercial interest & poor strategic planning (10%)

10-15 years to develop, cost \$1 billion to develop one successful medication.

KEY WORDS

Drug development;
Drug optimization;
Clinical trial;
Structure–tissue exposure/
selectivity relationship
(STR);
Structure–tissue exposure/
selectivity–activity
relationship (STAR)

Abstract Ninety percent of clinical drug development fails despite implementation of many successful strategies, which raised the question whether certain aspects in target validation and drug optimization are overlooked? Current drug optimization overly emphasizes potency/specificity using structure–activity–relationship (SAR) but overlooks tissue exposure/selectivity in disease/normal tissues using structure–tissue exposure/selectivity–relationship (STR), which may mislead the drug candidate selection and impact the balance of clinical dose/efficacy/toxicity. We propose structure–tissue exposure/selectivity–activity relationship (STAR) to improve drug optimization, which classifies drug candidates based on drug’s potency/selectivity, tissue exposure/selectivity, and required dose for balancing clinical efficacy/toxicity. Class I drugs have high specificity/potency and high tissue exposure/selectivity, which needs low dose to achieve superior clinical efficacy/safety with high success rate. Class II drugs have high specificity/potency and low tissue exposure/selectivity, which requires high dose to achieve clinical efficacy with high toxicity and needs to be cautiously evaluated. Class III drugs have relatively low (adequate) specificity/potency but high tissue exposure/selectivity, which requires low dose to achieve clinical efficacy with manageable toxicity but are often overlooked. Class IV drugs have low specificity/potency and low tissue exposure/selectivity, which achieves inadequate efficacy/safety, and should be terminated early. STAR may improve drug optimization and clinical studies for the success of clinical drug development.
